Series	The central objective of the Canadian Community Health Survey (CCHS) is to gather health-related data at the sub-provincial levels of geography (health region or combined health regions).
<p>Abstract</p> <p>The Canadian Community Health Survey (CCHS) is a cross-sectional survey that collects information related to health status, health care utilization and health determinants for the Canadian population. The CCHS operates on a two-year collection cycle. The first year of the survey cycle “.1” is a large sample, general population health survey, designed to provide reliable estimates at the health region level. The second year of the survey cycle “.2” has a smaller sample and is designed to provide provincial level results on specific focused health topics.</p> <p>This Microdata File contains data collected for CCHS Cycle 3.1 between January 2005 and December 2005. The CCHS Cycle 3.1 collects responses from persons aged 12 or older, living in private occupied dwellings in 122 health regions covering all provinces and territories. Excluded from the sampling frame are individuals living on Indian Reserves and on Crown Lands, institutional residents, full-time members of the Canadian Forces, and residents of certain remote regions. The CCHS covers approximately 98% of the Canadian population aged 12 and over.</p> <p>CCHS 3.1 Survey consists of the main survey files and 3 sub-sample files</p> <p>Sub-sample 1: Health Utility Index (HUI), Fruit and Vegetable Consumption and Labour Force (long form)</p> <p>Sub-sample 2: Measured Height and Weight</p> <p>Sub-sample 3: Access to Health Care Services, Waiting Times and Patient Satisfaction (replaces the Health Services Access Survey (HSAS))</p>

Universe

The CCHS targets persons aged 12 years and older who are living in private dwellings in the ten provinces and three territories. Persons living on Indian Reserves or Crown lands, those residing in institutions, full-time members of the Canadian Forces and residents of certain remote regions are excluded from this survey. The CCHS covers approximately 98% of the Canadian population aged 12 and older.

Sampling**Sampling Procedure**

Stratified random sample

Response RateSee section 9. http://odesi.scholarsportal.info/documentation/HEALTH/CCHS/2005/DOCS/guide_e.pdf**Weighting**

WTSE_M = Weights - Master

The principle behind estimation in a probability sample such as the CCHS Cycle 3.1 is that each person in the sample "represents", besides himself or herself, several other persons not in the sample. For example, in a simple random 2% sample of the population, each person in the sample represents 50 persons in the population. In the terminology used here, it can be said that each person has a weight of 50.

The weighting phase is a step that calculates, for each person, his or her associated sampling weight. This weight appears on the PUMF, and must be used to derive meaningful estimates from the survey. For example, if the number of individuals who smoke daily is to be estimated, it is done by selecting the records referring to those individuals in the sample having that characteristic and summing the weights entered on those records.

Details of the method used to calculate sampling weights are presented in Section 8. http://odesi.scholarsportal.info/documentation/HEALTH/CCHS/2005/DOCS/guide_e.pdf

Data Processing & Appraisal**Estimates of Sampling Error**

Since it is an unavoidable fact that estimates from a sample survey are subject to sampling error, sound statistical practice calls for researchers to provide users with some indication of the magnitude of this sampling error. The basis for measuring the potential size of sampling errors is the standard deviation of the estimates derived from survey results. However, because of the large variety of estimates that can be produced from a survey, the standard deviation of an estimate is usually expressed relative to the estimate to which it pertains. This resulting measure, known as the coefficient of variation (CV) of an estimate,

is obtained by dividing the standard deviation of the estimate by the estimate itself and is expressed as a percentage of the estimate.

For example, suppose hypothetically that it is estimated that 25% of Canadians aged 12 and over are regular smokers and that this estimate is found to have a standard deviation of 0.003. Then the CV of the estimate is calculated as:

$$(0.003/0.25) \times 100\% = 1.20\%$$

Statistics Canada commonly uses CV results when analyzing data and urges users producing estimates from the CCHS Cycle 3.1 data files to also do so. For details on how to determine CVs, see Section 11. For guidelines on how to interpret CV results, see the table at the end of Subsection 10.4.
